

1. Write a function called `greet` that takes no input and prints "Welcome to Python!". Call it three times in a row.
2. Write a function called `print_divider` that prints a line of twenty dashes. Use it to separate three different `print()` messages of your choice.
Hint: define it once at the top, then call `print_divider()` between each message.
3. Write a function called `show_menu` that prints three numbered options on separate lines. Call the function, then try calling it again without the parentheses and compare what happens.
Hint: `show_menu()` runs it; `show_menu` alone does nothing at all, silently.
4. Write two small functions of your own, each printing a different message, and call them in an order that tells a short story (for example: opening a shop, then closing it).
5. A program calls `announce()` as its very first line, and only defines `announce()` underneath, further down the file. Running it raises a `NameError`. Fix the program so it runs without error, without changing what either line does.

Hint: Python must see a function's `def` before the line that calls it — think about which block needs to move.
