

1. Given marks = [45, 67, 89, 34, 90], print how many marks there are, the total of all marks, and the average rounded to 2 decimal places.

2. Given langs = ["Python", "SQL", "Java", "C++"], print the first item, the last item, and the middle two items — using indexing and one slice.

3. Given nums = [12, 7, 3, 12, 25, 8, 7], print the list sorted smallest to largest without changing the original, then print the original to prove it is unchanged.

*Hint: sorted(nums) returns a new list; nums.sort() changes the original and returns None.*

4. Given items = ["Notebook", "Pen", "Bag"] and prices = [45, 10, 899], print the name of the most expensive item — not just its price.

*Hint: max(prices) gives the highest price; prices.index(...) gives the position it sits at, and the same position in items is the matching name.*

5. Given nums = [12, 7, 3, 12, 25, 8, 7], build a new list with the duplicates removed, keeping the original order, and print it.

*Hint: start with an empty list and only append a number when it is not in that new list yet.*
