

1. Given `fruits = ["apple", "banana"]`, append "cherry" to the end, then insert "kiwi" at index 1. Print the final list.
2. Given `nums = [10, 20, 30, 20]`, remove the first occurrence of 20, then pop the last item from what remains. Print the popped value and the final list.
3. Given `scores = [4, 1, 3, 2]`, sort the list in descending order using `.sort()` with the `reverse` argument, then print it.
4. Given `colors = ["red", "blue", "red", "green", "red"]`, find how many times "red" appears and the index of its first occurrence, then print a single sentence combining both results, like "red appears 3 times, first at index 0".

*Hint: Use `colors.count("red")` and `colors.index("red")` to get the two numbers, then drop them into a formatted string with `.format()` or an f-string.*
