

1. Given `student = {"name": "Asha", "age": 21, "marks": 88}`, print the value for "name" using square brackets, and the value for "grade" using `get()` with a default of "N/A".

*Hint: `student["name"]` would crash for a missing key; `get()` with a default never does.*

2. Given an empty dictionary, add three key-value pairs of your choice one at a time, printing the dictionary after each addition.

3. Given `book = {"title": "Wings of Fire", "price": 250}`, update the price to 300, add a new key "author", then print the final dictionary.

*Hint: the same square-bracket assignment adds a new key or updates an existing one.*

4. Given `item = {"name": "Pen", "price": 10, "stock": 50}`, remove "stock" using `del`, then remove "price" using `pop()` and print the value that `pop()` returned.

*Hint: `del` removes silently; `pop()` removes and hands back the value.*

5. Given `contact = {"phone": {"home": "011-2345", "mobile": "98765"}}`, print only the mobile number using nested key lookups, then check and print whether "email" exists as a top-level key.

*Hint: `contact["phone"]["mobile"]` reads left to right. Use `in` on `contact` directly for the second part.*
