

1. Given `marks = {"asha": 88, "ravi": 92, "meera": 79}`, print all the names, all the marks, and all the (name, mark) pairs, using `keys()`, `values()` and `items()`.

*Hint: wrap each in `list()` to see them clearly, e.g. `list(marks.keys())`.*

2. Using the same `marks` dictionary, loop with `items()` to print each name and mark on its own line in the format `"asha scored 88"`.

*Hint: for name, mark in marks.items():*

3. Given `a = {"x": 1, "y": 2}` and `b = {"y": 9, "z": 3}`, update `a` with `b` and print the result. Explain in a comment what happened to the value of `"y"`.

*Hint: `a.update(b)` overwrites any key that exists in both.*

4. Given `marks = {"asha": 88, "ravi": 92, "meera": 79}`, print the name of the topper and the name of the lowest scorer, without sorting the dictionary manually.

*Hint: `max(marks, key=marks.get)` and `min(marks, key=marks.get)`.*

5. Given a sentence typed by the user, build a dictionary counting how many times each word appears, then print the word that appears the most.

*Hint: `split()` the sentence into words, use `counts.get(w, 0) + 1` to tally, then `max()` with a key to find the top word.*
