

100 Days of Python

Day 3 — Practice Assignment: Data Types in Python

- 1. Create one variable each of type `int`, `float`, `str`, and `bool`, then print each variable along with its type using `type()`.**
- 2. Take the string `num_str = "42"` and the float `pi_val = 3.14`. Convert `num_str` into an integer and `pi_val` into an integer, then print the results along with each new type.**

Hint: Use `int()` and `int()` again on the float — notice what happens to the decimal part.
