

100 Days of Python

Day 6 — Practice Assignment: Arithmetic Operators in Python

1. Take two numbers, $a = 15$ and $b = 4$. Print the result of addition, subtraction, multiplication, and division between them, each on its own line with a label.
2. You are splitting a restaurant bill of 850 rupees equally among 4 friends. Calculate and print how much each friend pays, and how much money is left over (if the split isn't exact).

Hint: Use `//` for the equal share and `%` to find the leftover amount.

3. Write a program that calculates the area of a rectangle with length = 12 and width = 5, then prints the result using the exponent operator to also show the width squared separately.

Hint: Use `**` for the exponent, e.g. `width ** 2`.

4. You are building a simple travel planner. A trip covers distance = 540 km and the car covers 18 km per litre. Calculate and print how many litres of fuel are needed, rounding up so you never run short.

Hint: Regular division gives a decimal — think about how `//` and an extra `+1` could help you round up.
