

# 100 Days of Python

Day 7 — Project 01: Personal Profile Generator

---

## Project Brief

Build a program that collects a user's personal details using `input()`, calculates their age from the birth year, and then prints a neatly formatted profile card — combining everything you have learned so far: variables, data types, type conversion, arithmetic operators, and input/output.

## Requirements

- 1 Print a header titled PERSONAL PROFILE GENERATOR, surrounded by a line of "=" characters.
- 2 Using `input()`, ask the user to enter: name, birth year, gender, city, profession, course, skills, career goal, hobby, and email.
- 3 Calculate the user's age using the current year and the entered birth year (convert the birth year to an integer first).
- 4 Print a second section titled PERSONAL PROFILE, again surrounded by a line of "=" characters.
- 5 Under this section, print each detail as a neat label-colon-value row (e.g. Name : Aarav Sharma), with the Age row showing the calculated age followed by "Years".
- 6 End the program with a closing banner that says Profile Generated Successfully, surrounded by a line of "=" characters.

*Hint: To line up the colons neatly like in the sample output, use an f-string with padding, e.g. `print(f'{'Name':<12}: {name}')` — the < and number control the spacing.*

## Bonus Challenge

Split the skills entered (e.g. "Python, SQL") into a list and print how many skills the user has listed, right below the Skills row.
