

100 Days of Python

Day 22 — Practice Assignment: Introduction to Strings

1. Store your name in a variable as a string and print both the string itself and its length using `len()`.

Hint: `len()` counts every character in the string, including spaces.

2. Using indexing, print the first character, the last character, and the third character of the string `word = "Python"`.

Hint: Use `word[0]` for the first character and `word[-1]` for the last — indexing starts at 0, not 1.

3. You are given two strings: `first = "Py"` and `second = "thon"`. Concatenate them into a single word and print it, then concatenate them again with a space in between and print that too.

Hint: The `+` operator joins strings exactly as they are — add `" "` as its own piece if you want a space in between.

4. You're building a simple login system. Given `username = "coder_22"`, print a welcome message that includes the username, the first character of the username, and the total number of characters in it using `len()`.

Hint: Combine indexing, concatenation, and `len()` together — build the message piece by piece with `+`.
