

**1. Given the string `word = "Elephant"`, print the character at index 0, the character at index 3, and the last character using negative indexing.**

*Hint: Negative indices count from the end — `word[-1]` is always the last character, no matter how long the string is.*

**2. Given phrase = "Python is fun", print the first 6 characters and the last 3 characters using slicing.**

*Hint: `phrase[:6]` grabs everything up to (but not including) index 6; `phrase[-3:]` grabs the last 3 characters.*

**3. Given `code = "ABCDEFGH"`, print every other character starting from index 0, then print the string reversed.**

*Hint: A slice takes a step too — `code[::2]` skips by 2, and `code[::-1]` walks backward through the whole string.*

**4. You're validating a product code = "PRD-4521-X". Print the first 3 characters, the middle section between the dashes, and the final character, then combine them into a single formatted message using concatenation.**

*Hint: Slice out each piece separately (`code[0:3]`, `code[4:8]`, `code[-1]`) before joining them together with `+`.*
