

1. Write a function `make_sandwich` with parameters `bread`, `filling` (default `"cheese"`) and `toasted` (default `False`). Call it three times: with only `bread`, with `bread` and `toasted` set using a keyword, and with both `filling` and `bread` named as keywords in reversed order.
2. Write a function `event` with parameters `name`, `date` and `location` (default `"TBD"`). Call it with `name` and `date` positional, and `location` passed as a keyword argument.

3. Write a function `describe_trip` with parameters `destination`, `days` and `budget`. Call it with `destination` positional and both `days` and `budget` as keyword arguments, in any order you like.

*Hint: once the first positional argument is given, every argument after it must be named.*

4. Given `def add(a, b): print(a + b)`, explain in a comment exactly why `add(a=1, a=2)` fails, and separately why `add(a=1, c=2)` fails — the two errors are not the same kind.

*Hint: one is a `SyntaxError` caught by Python itself; the other is a `TypeError` caught when the function is actually called.*

5. Write a function `build_profile` with parameters `name`, `age` (default `18`) and `city` (default `"Unknown"`). Call it in a way that sets `city` but leaves `age` at its default, without supplying `age` at all.

*Hint: this is only possible by naming `city` as a keyword argument.*
